#### Introduction

- The pine wood nematode (PWN) Bursaphelenchus xylophilus (Steiner and Buhrer) Nickle is the causal agent of the pine wilt disease.
- Native to North America (USA and Canada), it has invaded Japan, China, Korea, Portugal, and Spain recently, where it can cause up to 80% - 90% tree mortality, leading to huge economic impacts to the forest sector.
- In Europe, Monochamus galloprovincialis (Olivier) is currently the only identified vector of PWN.
- EU regulations require clear-cutting a 500-m-radius circle around infested trees (European Commission, 2015). However, this radius is too small to eradicate PWN according to previous studies.
- Alternative: selective-cutting on a tree-by-tree basis with intensive surveillance.

#### **Research question**

Visual surveillance of

 Which strategy is the most cost-effective: Clear-cutting (CC) or selective-cutting (SC)?

Trapping networks for

Figure 1. Concepts of two strategies.

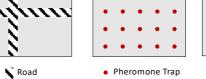

#### Materials and methods

An individual based model: vector dispersal, and PWN transmission via vector feeding and egg laying A 20 km \* 20 km homogeneous non-fragmented forest in Southwestern France

- Surveillance: visual, visual+trapping, or aerial Confirmation: wood sampling and lab confirmation Control of PWN-infested trees: logging and chipping CC or SC
- Cost: surveillance costs, wood sampling costs, eradication costs and revenue loss
  Effectiveness: net reproductive number (R<sub>cases</sub>), which is the net multiplication factor of infested trees

symptomatic trees from insect vectors symptomatic trees the ground

Aerial surveillance of

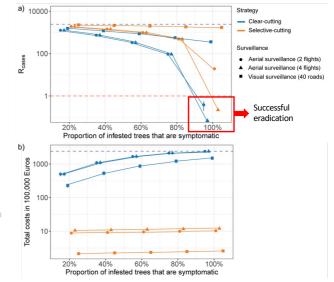

Figure 2. Concepts of three surveillance methods.

## Results and conclusion (Sun et al., submitted)

- SC with intensified aerial surveillance allows eradicating PWN (net reproductive number: R<sub>cases</sub> < 1) with ~200-fold lower costs than CC provided 100% of the infested trees are symptomatic;
- Containment would be more realistic than eradication if PWN is introduced into the areas where not all infested trees can be detected and vector beetles are at high population level.
- Aerial surveillance is more efficient than ground surveillance.
- SC is always more cost-effective than CC for the same level of effectiveness, as it saves the costs of cutting healthy trees.
- Overall, these results highlight the need to revise EU policy on PWN management to allow the more cost-effective selective-cutting strategy in non-fragmented pine forest.
