

Epidemiological modelling and the basic reproduction number, R_0

Alexey Mikaberidze¹ and Nik Cunniffe²

¹University of Reading, UK; ²University of Cambridge, UK

What is the basic reproduction number, R_0 ?

 susceptible host

 infected host

What is the basic reproduction number, R_0 ?

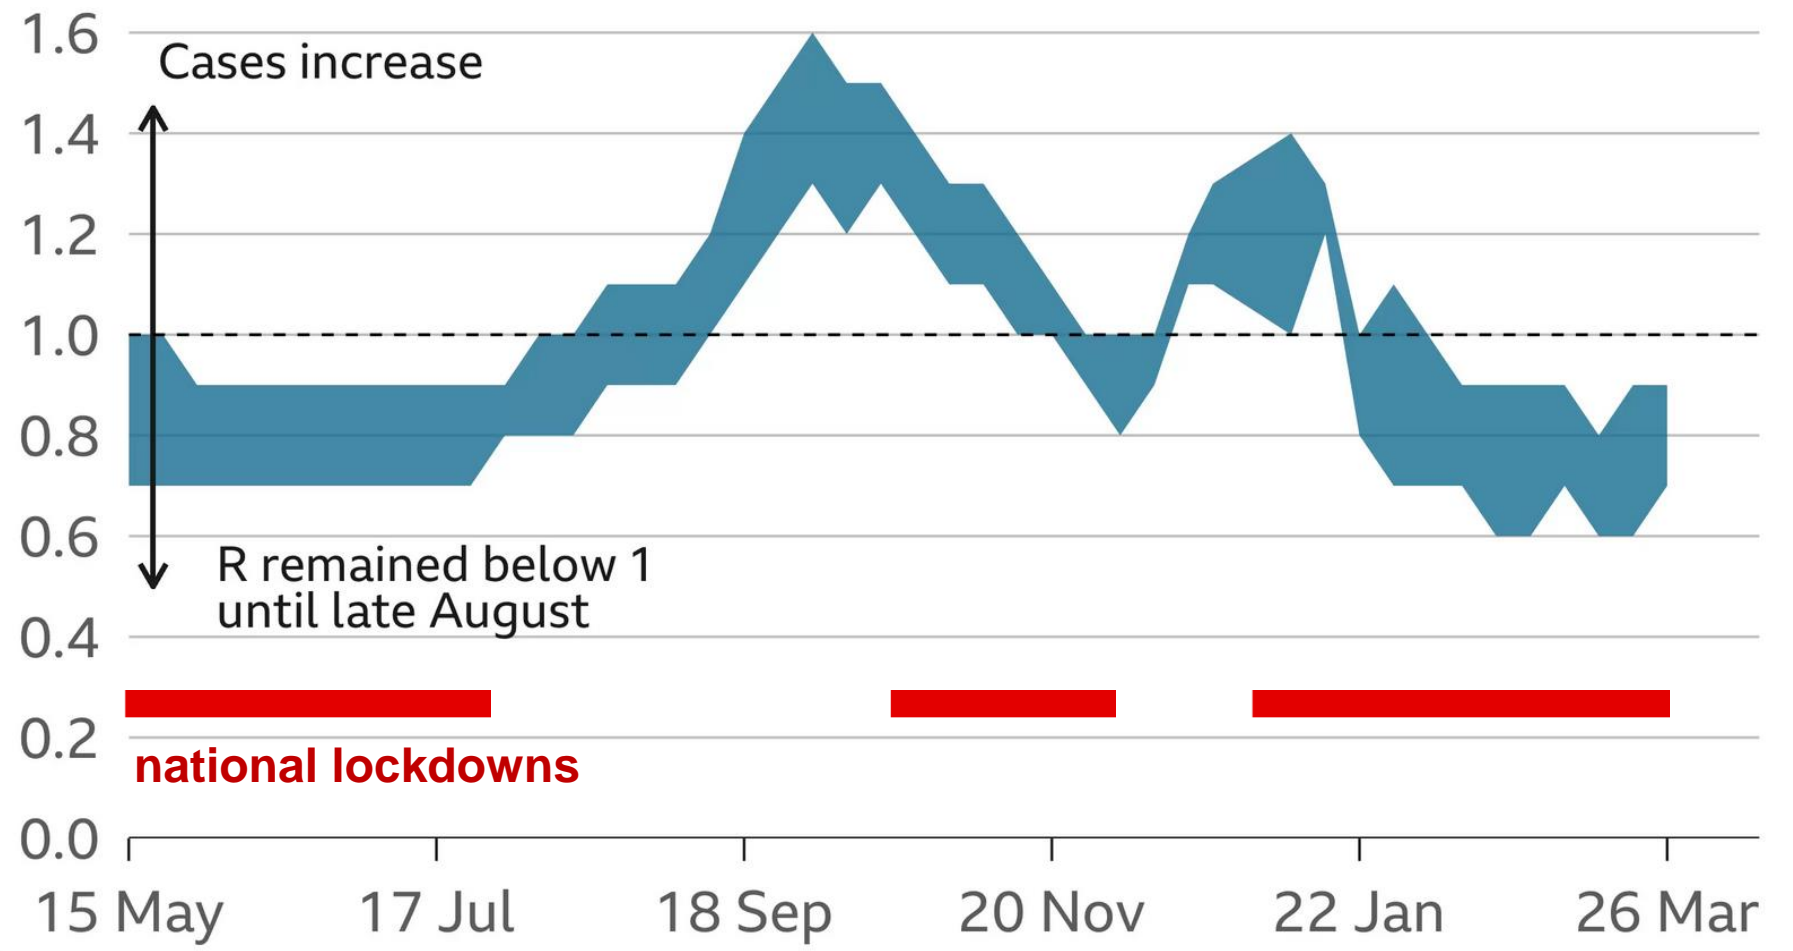

$$R_0 = 4$$

 susceptible host

 infected host

"R number" for COVID-19 in 2020-2021 in the UK

Source: gov.uk website

Outline

1. What is R_0 and what it can be used for?
2. Estimating R_0 for potato late blight
3. Methods of calculating R_0
4. R_0 across space: from fields to landscapes
5. Epidemiological modelling \leftrightarrow remote sensing

What is the basic reproduction number R_0 for plant diseases?

-  susceptible host
-  infected host
-  removed host

$$R_0 = 4$$

What is the basic reproduction number R_0 for plant diseases?

1. What are host units?
2. Space is important
3. Plants do not (usually) recover

How modelling and R_0 can be used to improve disease management

Gain a mechanistic understanding of how diseases spread

R_0 as epidemic threshold

R_0 as measure of pathogen fitness

Understand how pathogens adapt to control measures

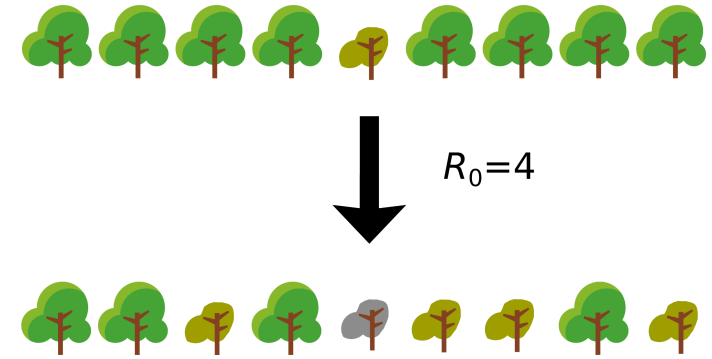

R_0 as measure of competitive capacity

Devise mathematical models to inform disease management

R_0 as metric for monitoring

R_0 as indication of success

R_0 across space

3. cultivated landscapes

2. fields (or orchards)

1. plants/leaves

What is R_0 for potato late blight?

FIG. 4.1. Progress of blight on potatoes caused by *Phytophthora infestans*. The top half shows the increase of x , and the bottom half the increase of $\log_{10}[x/(1-x)]$, with time. Data of Large (1945). A, variety Majestic, Dartington, 1943; B, variety Majestic, Dartington, 1942; C, variety Majestic, Kentisbeare, 1942; D, variety Majestic, Durnsford, 1944; E, variety Arran Consul, Dartington, 1941.

Question

Can we fit an SIR type model to van der Plank's Epidemic B to find R_0 ?

Potato late blight. Classical approach

FIG. 4.1. Progress of blight on potatoes caused by *Phytophthora infestans*. The top half shows the increase of x , and the bottom half the increase of $\log_{10}[x/(1-x)]$, with time. Data of Large (1945). A, variety Majestic, Dartington, 1943; B, variety Majestic, Dartington, 1942; C, variety Majestic, Kentisbeare, 1942; D, variety Majestic, Durnsford, 1944; E, variety Arran Consul, Dartington, 1941.

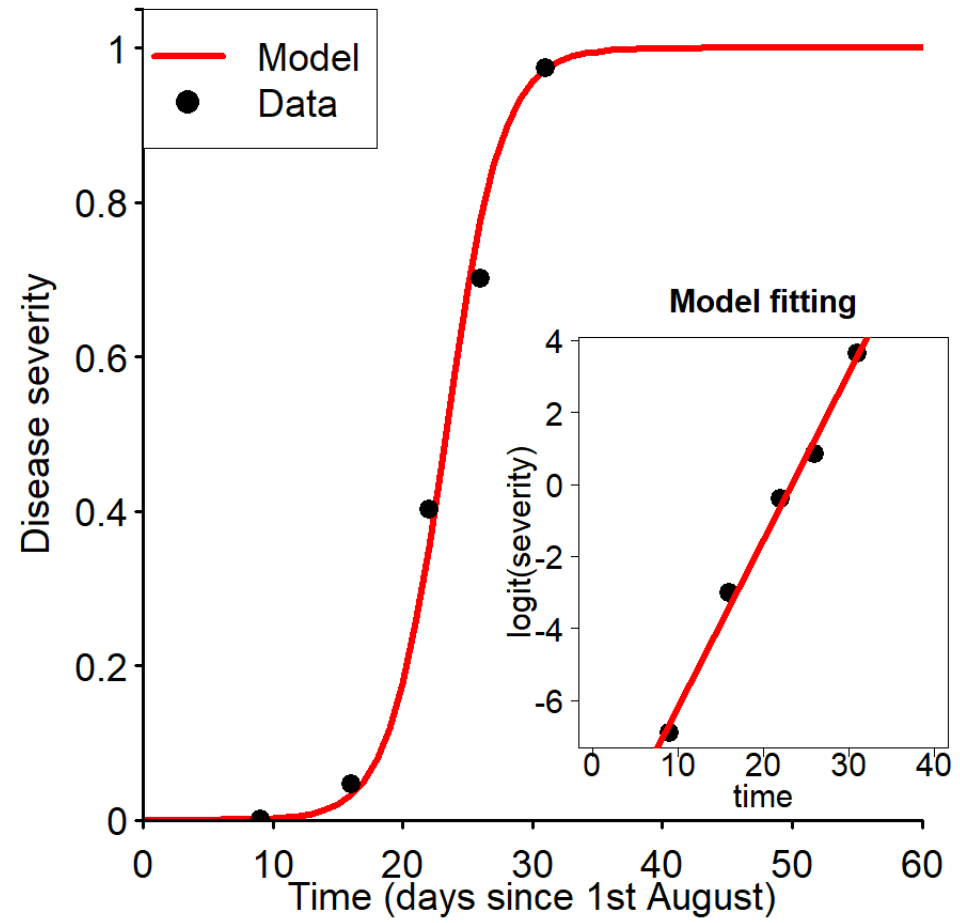

Polycyclic epidemic

Try logistic growth

$$y = \frac{1}{1 + (1/y_0 - 1)\exp(-rt)}$$

Various ways to find y_0 and r , e.g., regression of logit

Logistic model ($r=0.465$ per day, $y_0=1.964e-05$)

A compartmental model

Susceptible
S

Infected
I

Removed
R

Divide population into classes according to disease status

(S)usceptible Healthy (& not infected)

(I)nfected Infected (& actively infecting others)

(R)emoved Dead/post-infectious

Must decide on a scale; use “infectable site” (area of leaf covered by lesion)

Omit latent period for now (could be added easily; see later)

Assume total population is constant (no birth/death; could be relaxed easily)

A compartmental model

Infection

A single **susceptible** site becomes **infected**

Net rate depends on numbers of **susceptible** and **infected** sites

Removal

A single infected site becomes **removed** (dead/post-infectious)

Net rate depends on number of **infected** sites only

A compartmental model

β = rate of infection
(per susceptible,
per infected)

μ = rate of removal
(infectious period is $1/\mu$)

$$\frac{dS}{dt} = -\beta I S$$

$$\frac{dI}{dt} = \beta I S - \mu I$$

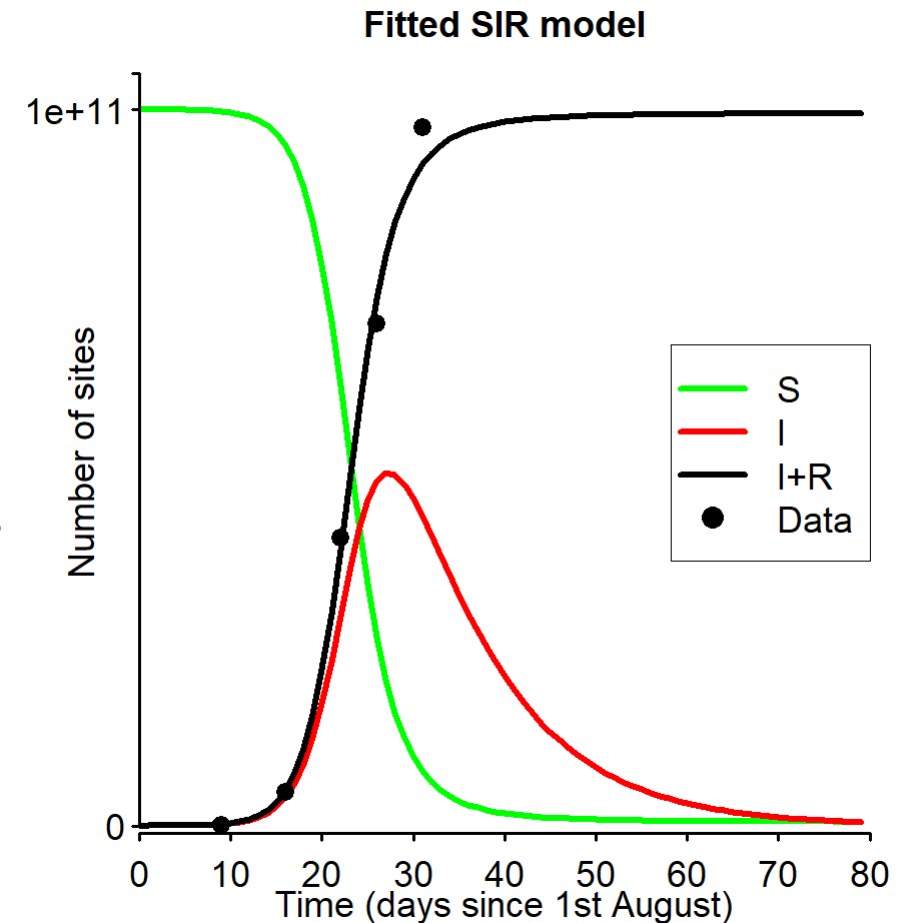

$$\frac{dR}{dt} = \mu I$$

Fitting the model

Experiment	Time	Severity
B	9	0.001
B	16	0.047
B	22	0.402
B	26	0.701
B	31	0.975

- Fit $I + R$ from model to Severity by least squares
- Assume $N = 1 \times 10^{11}$ and $\mu = 0.1 \text{ day}^{-1}$
- Free parameters to fit are β and $I(0)$

So, what is R_0 for potato late blight?

- R_0 = **Number of new infections** caused by a **single infected individual** introduced into a **totally susceptible population**
- R_0 = **Infection Rate** x **Population Size** x **Infectious Period** = $\beta \times N \times \frac{1}{\mu} = \frac{\beta N}{\mu}$
- For van der Plank's Epidemic B (assuming N and μ and fitting β and $I(0)$)

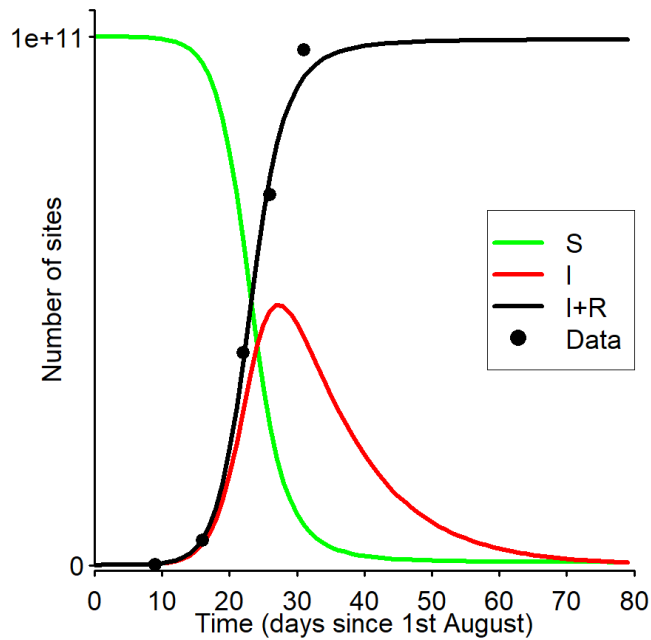

$$R_0 \approx \frac{1 \times 10^{11} \times 5.24 \times 10^{-12}}{0.1} \approx 5.24$$

Do assumptions matter?

Original Fit

Fitted SIR model

$$N = 1 \times 10^{11}, \beta \sim 5.24 \times 10^{-12}, \mu = 0.1$$

$$R_0 \sim 5.24$$

Alter number of sites (N)

Fitted SIR model

$$N = 1 \times 10^8, \beta \sim 5.24 \times 10^{-9}, \mu = 0.1$$

$$R_0 \sim 5.24$$

Alter infectious period ($1/\mu$)

Fitted SIR model

$$N = 1 \times 10^{11}, \beta \sim 4.44 \times 10^{-12}, \mu = 0.05$$

$$R_0 \sim 8.88$$

A simple way of finding R_0 you may see

A threshold for initial spread extracted from $dI/dt(0)$

$$\frac{dS}{dt} = -\beta I$$

$$\text{At } t = 0 \quad \frac{dI}{dt} \approx \beta I/N - \mu I$$

$$\frac{dI}{dt} = \beta I/S - \mu I$$

And R_0 is just the quantity that needs to be **greater than one** to make $dI/dt(0) > 0$, i.e. $R_0 = \frac{\beta N}{\mu}$

$$\frac{dR}{dt} = \mu I$$

Very **simple**, but only easy when models have **single infectious class**; true R_0 can also be ambiguous

In practice we use **Next Generation Matrix**; see later

Extension. SEIR model (adding latent period)

Rate of change of
Susceptible sites

$$= - \text{Infection}$$

Rate of change of
Exposed sites

$$= + \text{Infection} - \text{Gain of infectivity}$$

Rate of change of
Infectious sites

$$= + \text{Gain of infectivity} - \text{Removal}$$

Rate of change of
Removed sites

$$= + \text{Removal}$$

Extension. SEIR model (adding latent period)

$$\frac{dS}{dt} = -\beta SI$$

$$\frac{dE}{dt} = \beta SI - \sigma E$$

$$\frac{dI}{dt} = \sigma E - \mu I$$

$$\frac{dR}{dt} = \mu I$$

Finding R_0

Introduce an infectious host to population of size N

Exposed (i.e., latent) for $1/\sigma$; Infectious for $1/\mu$

Causes no new infections while Exposed

Causes infections at net rate βN while Infectious

$$R_0 = 0 \times \frac{1}{\sigma} + \beta N \times \frac{1}{\mu} = \frac{\beta N}{\mu} \quad (\text{precisely as before})$$

$$\begin{aligned} \frac{dS}{dt} &= -\beta SI \\ \frac{dE}{dt} &= \beta SI - \sigma E \\ \frac{dI}{dt} &= \sigma E - \mu I \\ \frac{dR}{dt} &= \mu I \end{aligned}$$

The construction of next-generation
matrices for compartmental
epidemic models

O. Diekmann¹, J. A. P. Heesterbeek^{2,*}, and M. G. Roberts³

Finding R_0 in practice

- These models were **simple** enough to **reason out** the form of R_0
- But this can be **hard**, particularly if “generation” is unclear, e.g., multiple host types
- Gold standard is “**Next Generation Method**”
- **Embeds discrete time** model in the (**continuous time**) compartmental model
- Underlying maths looks (is!) frightening, but boils down to **just a calculation**
- Tutorial introduction in **Diekmann *et al.* (2010) *J. Roy. Soc. Interface*: 7:873–885.**

Next generation method for SEIR model

$$\frac{dS}{dt} = -\beta SI$$

$$\frac{dE}{dt} = \beta SI - \sigma E$$

$$\frac{dI}{dt} = \sigma E - \mu I$$

$$\frac{dR}{dt} = \mu I$$

Next generation method for SEIR model

Focus on vector of **infected** hosts: $\mathbf{x} = (E, I)^T$

Model is $\frac{d\mathbf{x}}{dt} = \mathbf{F}(\mathbf{x}) - \mathbf{V}(\mathbf{x})$ where

$$\mathbf{F}(\mathbf{x}) = (\beta SI, 0)^T \quad \text{New infections}$$

$$\mathbf{V}(\mathbf{x}) = (\sigma E, \mu I - \sigma E)^T \quad \text{Transfers out}$$

R_0 is largest eigenvalue ("spectral radius") of $\mathcal{F}\mathcal{V}^{-1}$

where \mathcal{F} and \mathcal{V} are Jacobians of \mathbf{F} and \mathbf{V}

$$\frac{dS}{dt} = -\beta SI$$

$$\frac{dE}{dt} = \beta SI - \sigma E$$

$$\frac{dI}{dt} = \sigma E - \mu I$$

$$\frac{dR}{dt} = \mu I$$

Next generation method for SEIR model

$$F(\mathbf{x}) = (F_E, F_I)^T = (\beta SI, 0)^T$$

$$V(\mathbf{x}) = (V_E, V_I)^T = (\sigma E, \mu I - \sigma E)^T$$

$$\mathbf{x} = (E, I)^T$$

$$\mathcal{F} = \frac{\partial F_i}{\partial x_j} = \begin{pmatrix} \frac{\partial F_E}{\partial E} & \frac{\partial F_E}{\partial I} \\ \frac{\partial F_I}{\partial E} & \frac{\partial F_I}{\partial I} \end{pmatrix}$$

$$\mathcal{V} = \frac{\partial V_i}{\partial x_j} = \begin{pmatrix} \frac{\partial V_E}{\partial E} & \frac{\partial V_E}{\partial I} \\ \frac{\partial V_I}{\partial E} & \frac{\partial V_I}{\partial I} \end{pmatrix}$$

At DFE
|

Matrix inversion
→

$$\mathcal{V}^{-1} = \begin{pmatrix} 1/\sigma & 0 \\ 1/\mu & 1/\mu \end{pmatrix}$$

Next generation method for SEIR model

R_0 is the largest eigenvalue (“spectral radius”) of $\mathcal{F}\mathcal{V}^{-1}$

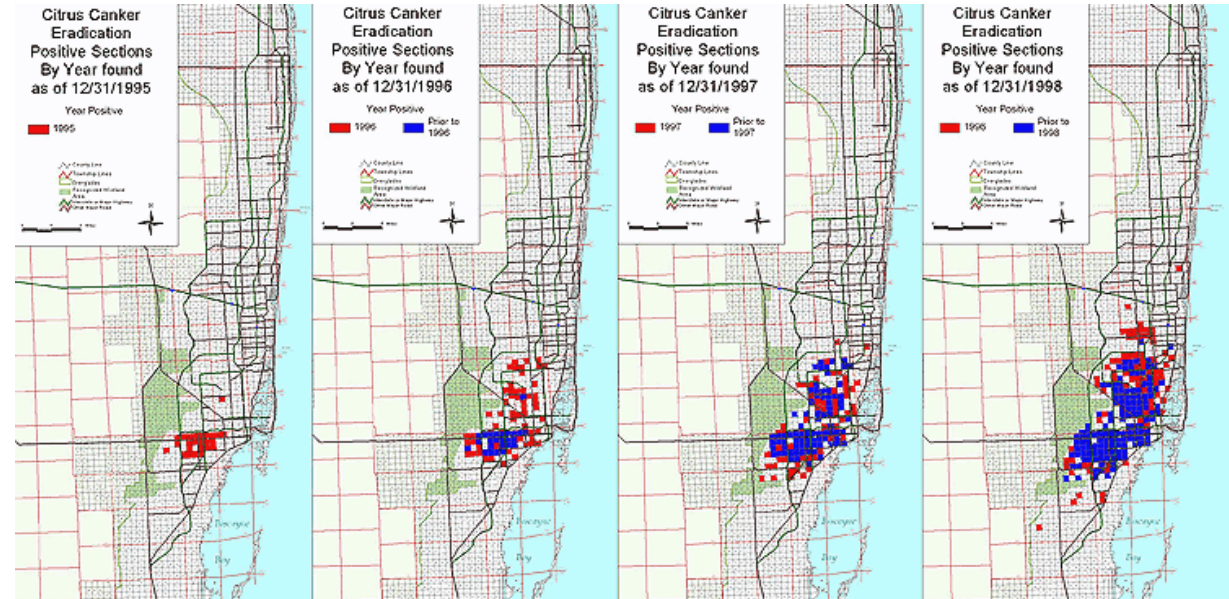

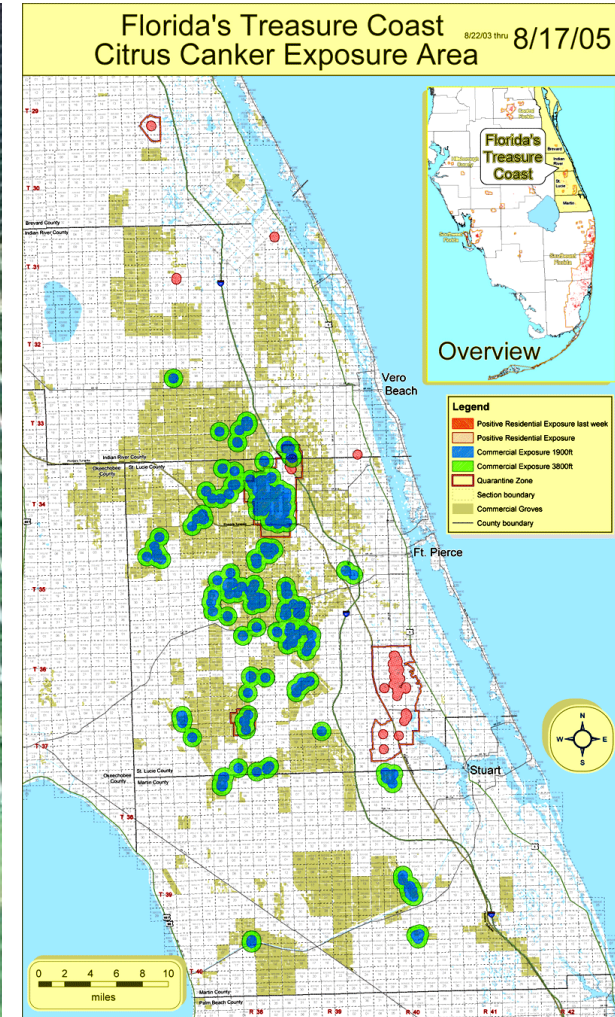

$$\mathcal{F}\mathcal{V}^{-1} = \begin{pmatrix} 0 & \beta N \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1/\sigma & 0 \\ 1/\mu & 1/\mu \end{pmatrix}$$

Eigenvalues are 0 and $R_0 = \frac{\beta N}{\mu}$

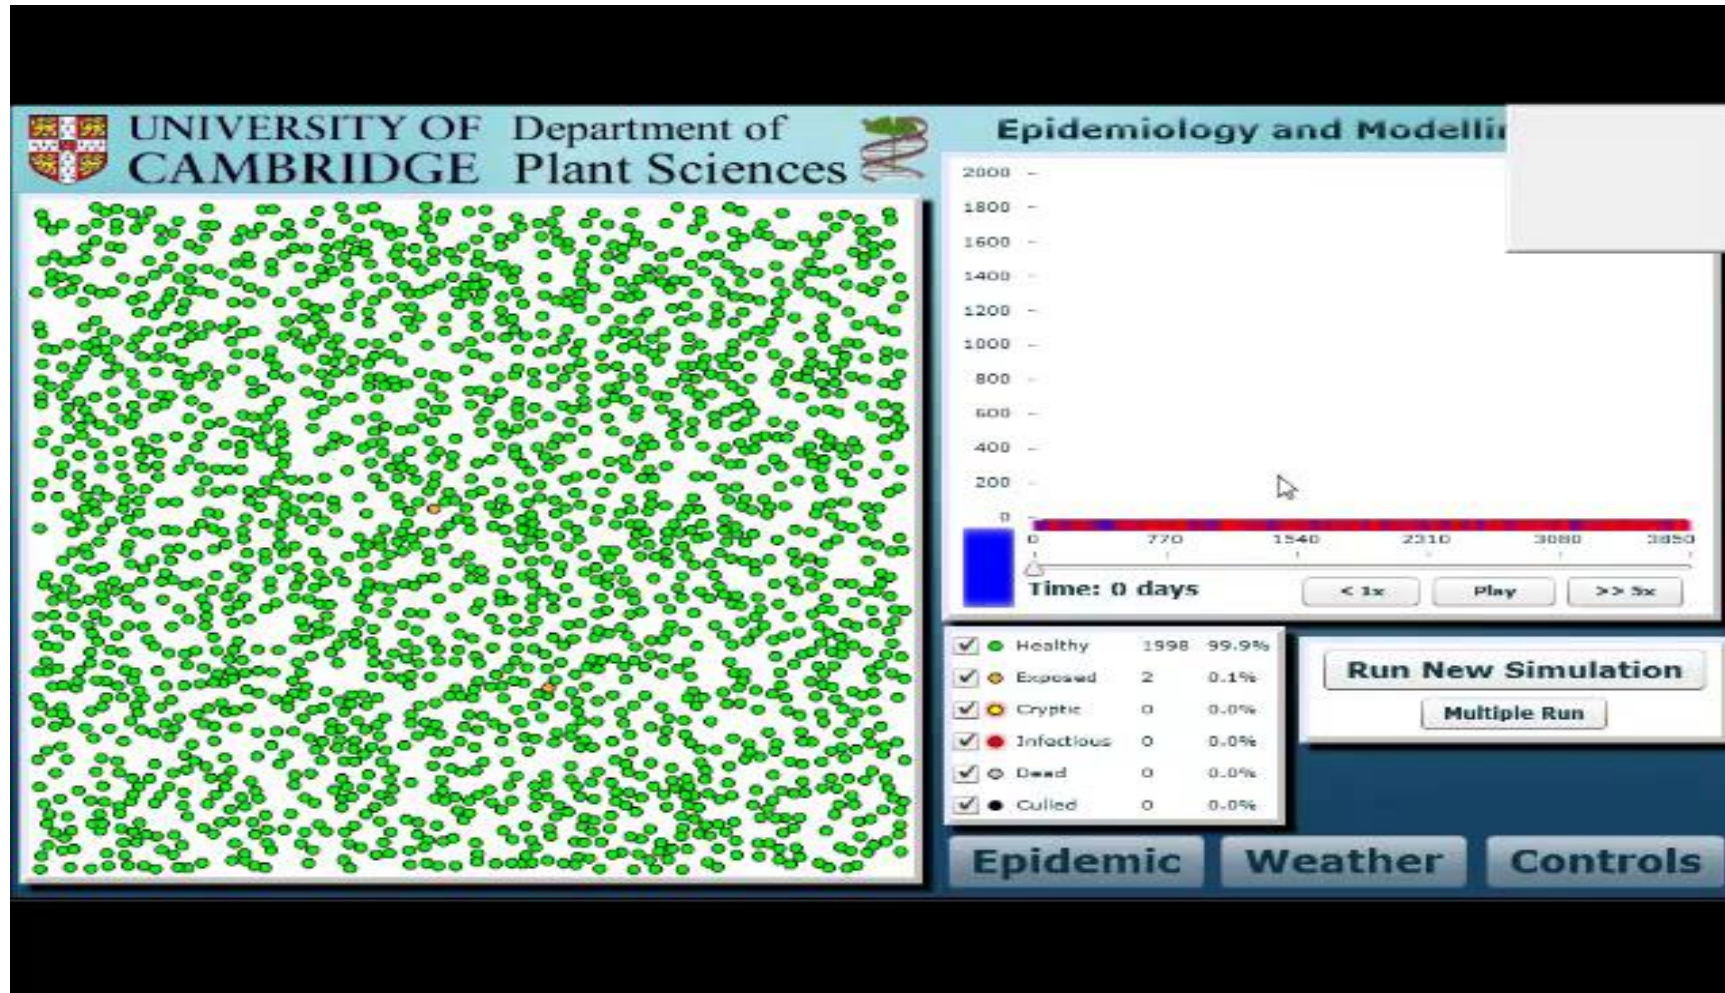

Same result, but no thinking required, instead just mindless (!) calculation

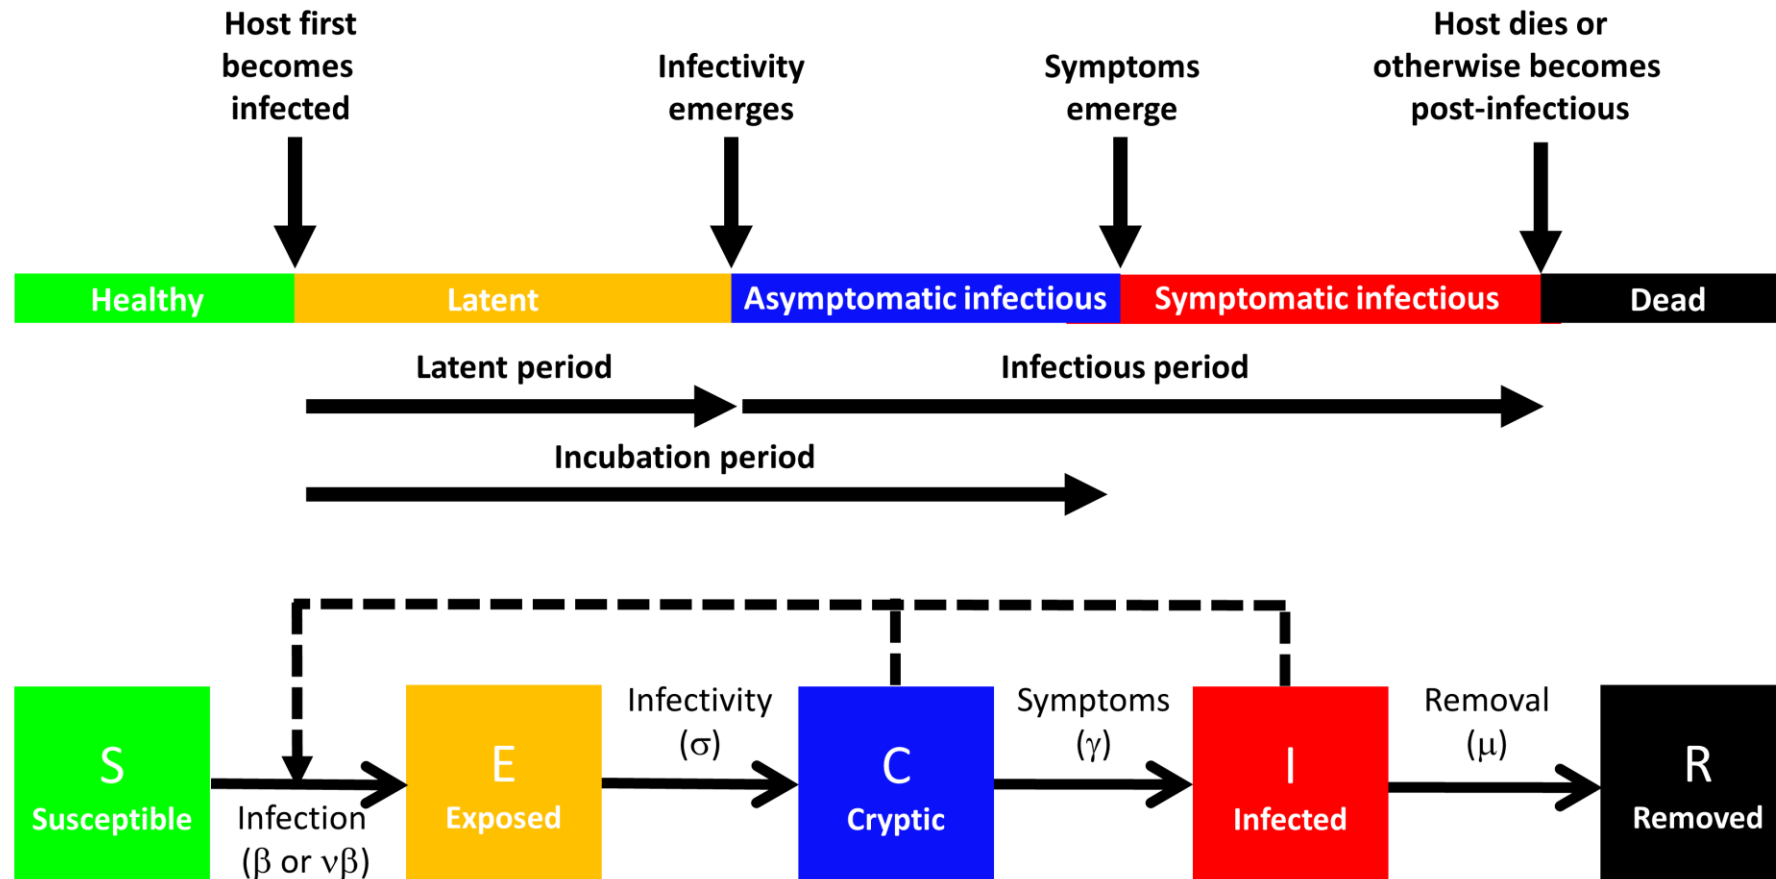

Using R_0 to understand control. Citrus canker

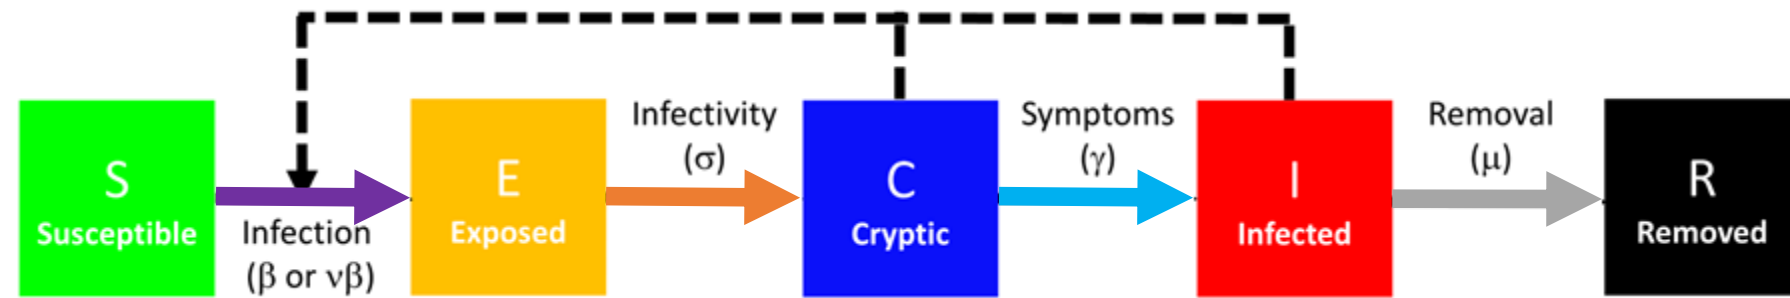

Using R_0 to understand control. Citrus canker

Can we use R_0 to see why culling is needed?

Modelling

Rate of change of
Susceptible trees

$$= - \text{Infection}$$

Rate of change of
Exposed trees

$$= + \text{Infection} - \text{Gain of infectivity}$$

Rate of change of
Cryptic trees

$$= + \text{Gain of infectivity} - \text{Emergence of symptoms}$$

Rate of change of
Infectious trees

$$= + \text{Emergence of symptoms} - \text{Removal (by roguing)}$$

Rate of change of
Removed trees

$$= + \text{Removal (by roguing)}$$

Modelling

$$\frac{dS}{dt} = -\nu\beta SC - \beta SI$$

$$\frac{dE}{dt} = \nu\beta SC + \beta SI - \sigma E$$

$$\frac{dC}{dt} = \sigma E - \gamma C$$

$$\frac{dI}{dt} = \gamma C - \mu I$$

$$\frac{dR}{dt} = \mu I$$

Finding R_0

$$\frac{dS}{dt} = -v\beta SC - \beta SI$$

$$\frac{dE}{dt} = v\beta SC + \beta SI - \sigma E$$

$$\frac{dC}{dt} = \sigma E - \gamma C$$

$$\frac{dI}{dt} = \gamma C - \mu I$$

$$\frac{dR}{dt} = \mu I$$

Introduce an infected host to population of size N

Exposed for $1/\sigma$; Cryptic for $1/\gamma$; Infected for $1/\mu$

Causes **no infections** while **Exposed**

infections at net rate $v\beta N$ while **Cryptic**

infections at net rate βN while **Infected**

$$R_0 = 0 \times \frac{1}{\sigma} + v\beta N \times \frac{1}{\gamma} + \beta N \times \frac{1}{\mu}$$

What does this mean?

We have found $R_0 = \frac{\nu\beta N}{\gamma} + \frac{\beta N}{\mu}$

But if we only rogue, **all we can affect is μ** (roguing rate)

Even if $\mu \rightarrow \infty$ (very frequent roguing), $R_0 \rightarrow \frac{\nu\beta N}{\gamma} > 1$

And so **cryptic infection** means **culling is necessary**

R_0 across space

3. cultivated landscapes

2. fields (or orchards)

1. plants/leaves

Is the pathogen more invasive in smaller or larger fields?

SIR model

$$\frac{dS}{dt} = -\beta I S$$

$$\frac{dI}{dt} = \beta I S - \mu I$$

SIR model, now with space

$$\frac{\partial S(x, y, t)}{\partial t} = -\beta \lambda(x, y) S(x, y, t)$$

$$\frac{\partial I(x, y, t)}{\partial t} = \beta \lambda(x, y) S(x, y, t) - \mu I(x, y, t)$$

Spatially explicit transmission

$$\frac{\partial S(x, y, t)}{\partial t} = -\beta \lambda(x, y) S(x, y, t)$$

$$\frac{\partial I(x, y, t)}{\partial t} = \beta \lambda(x, y) S(x, y, t) - \mu I(x, y, t)$$

force of infection

= $\kappa(r)$ dispersal kernel

$$\lambda(x, y) = \int_0^{d_x} du \int_0^{d_y} dv \kappa(x, y, u, v) I(u, v, t).$$

How to calculate R_0 : linear stability of disease-free equilibrium

$$I(x, y, t) = 0$$

$$\frac{\partial I(x, y, t)}{\partial t} = \beta \int_0^{d_x} du \int_0^{d_y} dv \kappa(x, y, u, v) I(u, v, t) \overbrace{S(x, y, t)}^K - \mu I(x, y, t)$$

How to calculate R_0 : linear stability of disease-free equilibrium

$$I(x, y, t) = 0$$

$$\frac{\partial I(x, y, t)}{\partial t} = \beta \int_0^{d_x} du \int_0^{d_y} dv \kappa(x, y, u, v) I(u, v, t) \overset{K}{\cancel{S(x, y, t)}} - \mu I(x, y, t)$$

solve the eigenvalue problem

R_0

How to calculate R_0 : linear stability of disease-free equilibrium

$$I(x, y, t) = 0$$

$$\frac{\partial I(x, y, t)}{\partial t} = \beta \int_0^{d_x} du \int_0^{d_y} dv \kappa(x, y, u, v) I(u, v, t) \overset{K}{\cancel{S(x, y, t)}} - \mu I(x, y, t)$$

$$I(x, y, t) = w(x, y)e^{\lambda t} \rightarrow \frac{\beta K}{\mu} \int_0^{d_x} du \int_0^{d_y} dv \kappa(r)w(u, v) = \sigma w(x, y)$$

$$\sigma = 1 + \lambda/\mu$$

R_0

How to calculate R_0 : linear stability of disease-free equilibrium

$$I(x, y, t) = 0$$

$$\frac{\partial I(x, y, t)}{\partial t} = \beta \int_0^{d_x} du \int_0^{d_y} dv \kappa(x, y, u, v) I(u, v, t) \overset{K}{\cancel{S(x, y, t)}} - \mu I(x, y, t)$$

solve the eigenvalue problem

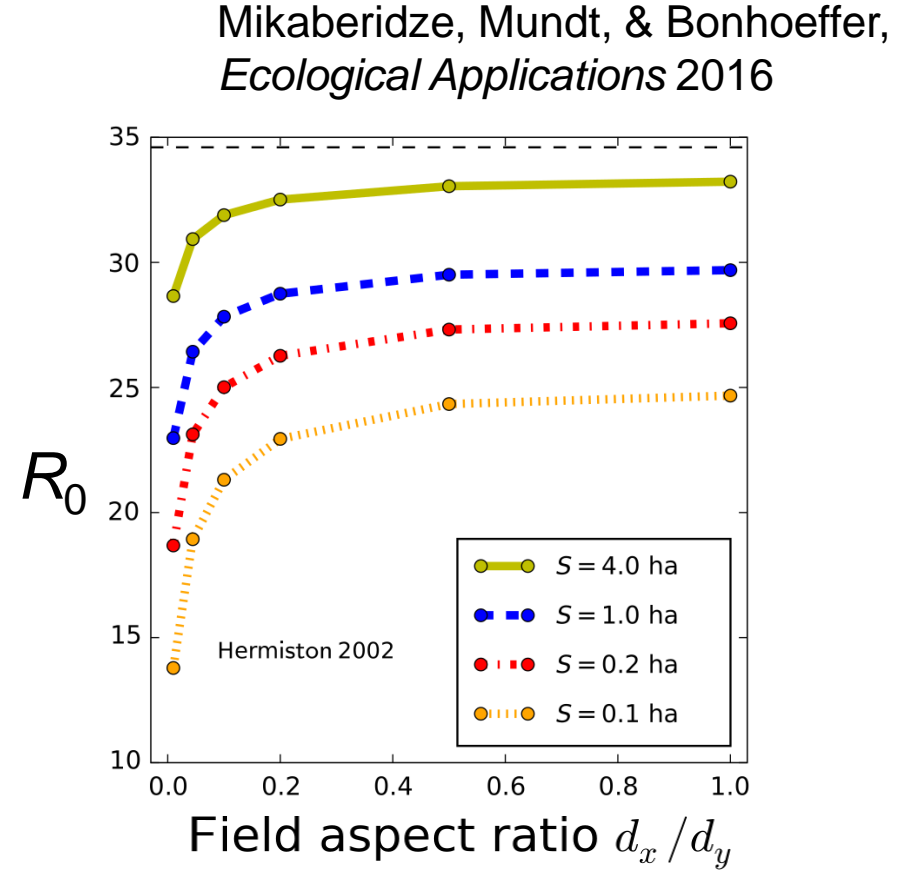

R_0

Smaller, more elongated wheat fields suppress the invasiveness of the pathogen (R_0) *Puccinia striiformis*

Mikaberidze, Mundt, & Bonhoeffer, *Ecological Applications* 2016

Smaller, more elongated wheat fields suppress the invasiveness of the pathogen (R_0) *Puccinia striiformis*

**We can use this insight to impede
pathogen adaptation to control measures**

R_0 for cultivated landscapes
depends on

landscape connectivity

landscape aggregation

$I(u, v, t)$

$S(x, y, t)$

Basic reproduction number R_0 depends on disease triangle
